

# FOREST HEALTH: Fire Behavior Considerations

#### Marty Alexander, PhD, RPF Senior Fire Behavior Research Officer Northern Forestry Centre Edmonton, Alberta malexand@nrcan.gc.ca

# Fire Behavior and the Forest Manager

"The behavior of fires is an important factor in the growth, harvesting, and regeneration of forest crops. How often fires occur and how hot they burn affect ... the ... quantity of products harvested from the forest. The forest manager may influence fire behavior by the nature of his operations ... it is important for forest managers to know fire behavior and to be able to evaluate the influence of forest management operations on it." – J.S. Barrows (1951)

# **Purpose of Presentation:**

Provide a overview (for the non-specialist) of relevant fire behavior terms and concepts, existing tools for predicting fire behavior at the stand level (with particular emphasis on crown fire), and finally, to offer some suggestions for future direction

# **Outline of Presentation:**

- I. Fire Behavior Fundamentals
- **II. Prediction of Fire Behavior**
- III. Conclusions and Suggestions on Future Direction

# I. "FIRE BEHAVIOR 101": The Fundamentals

Fire behavior is defined as the manner in which <u>fuel ignites</u>, <u>flame develops</u>, <u>fire spreads</u> and <u>exhibits other related</u> <u>phenomena</u> as determined by the interaction of fuels, weather, and topography (i.e., the fire environment).

# **Fire Environment Factors**

#### **Fuel Characteristics:**

- Quantity
- Moisture
- Size & Shape
- Depth/Height
- Arrangement

Weather Characteristics:

- Wind Speed & Direction
- Relative Humidity
- Air Temperature
- Rainfall Amounts & Duration
- Cloud Clover
- Atmospheric Instability

**Topographic Characteristics:** 

- Slope Steepness & Aspect
- Elevation
- Configuration
- Barriers to Fire Spread

# Nominal Spread Rates for Wildland Fires Ground or Subsurface Fires: < 0.01 m/min

Surface Backfires in Forests: 0.1 – 1.0 m/min

Surface Head Fires in Forests: 1 - 10 m/min

### **Crown Fires in Forests:**

15 - 200 m/min

Grass Fires: up to 250 - 350 m/min

# Basic Features of a Forest Fire: It spreads ...

it consumes or "eats" fuel and ...

it produces heat energy and light in

... a visible flaming combustion reaction.

### **Fire Intensity Spectrum**

- 10 kW/m Lower limit of surface fire spread
- 1000 kW/m Limit of suppression capability by hand crews

10 000 kW/m – Active crown fires have developed

100 000 kW/m – Major conflagrations

# Fire intensity is related to size of flames

Simple Formula for Field Use (for surface fires & intermittent crown fires)  $I = 300 \ge (L)^2$ L = Flame Length (metres)

For active crown fires, flame height ~ 2X stand height

**Extreme fire behavior** represents a level of fire activity that often precludes any fire suppression action. It usually involves one or more of the following:

- High Rate of Spread & Intensity
- Crowning
- Prolific Spotting
- Large Fire Whirls
- Well-developed
   Convection Column

# Comparison of Fire Behavior in a Pine Plantation under High Fire Danger Conditions (adapted from McArthur 1965)

Fire Description and	Stand A_	Stand B	
Characteristics	stics (pruned up to 5 m) (unpruned)		
Type of fire	Surface	Crown	
Forward spread rate (m/min)	5	10	
Fuel Consumed (t/ha)	18	28	
Head fire intensity (kW/m)	2700	8400	
Flame height (m)	2	12	
Fire area @ 1 hour (ha)	4.86*	19.44*	
Fire perimeter @ 1 hour (km	) 0.83	165	
Spotting distance (m)	<200	up to 2000	

\*Area enlargement = (Rate of Spread Increase)<sup>2</sup>

The more important fire behavior characteristics from the practical standpoint of fire suppression are:

- Forward Rate of Spread
- Fire Intensity
- Flame Front Dimensions

- Spotting Pattern (densities & distances)
- Fire Size and Shape
- Rate of Perimeter Increase
- Burn-out Time

# **II. Predicting Fire Behavior**

Systematic analysis that combines "art and science"

# The most effective means of appraising or evaluating potential fire behavior is considered to be the coupling of mathematical modelling with experienced judgement (e.g., "expert opinion"), and published case study knowledge (e.g., experimental, wild and prescribed fires)

#### Fuel dynamics and variation of flammability during the development of jack pine/black spruce stands **ELLEN MACDONALD** NATHALIE LAVOIE MARTY ALEXANDER University of Alberta NL1@gpu.srv.ualberta.ca University of Alberta emacdonald@ualberta.ca Canadian Forest Service malexand@NRCan.gc.ca **FIRE ENVIRONMENT EXPERT OPINION** Very little is known about the dynamics of the fuels during stand development and with time-since-fire ... We used about the variation of flammability the following methodology to learn more about the topic. **Fire Environment** Experimental Fires Expert Opinion **Fire Behavior** Expert Survey **Fire Behavior Models** the collective experience and the k of 50 forest fire behavior experts. sity of Albe 2002 The survey provided us with relevant information for the project based on a large number of fires -more than it is usually possible to observe and reproduce experimentally. lammability versus Time-Since-Fire We first selected 14 stands belonging to the same chronosequence and originating from a high intensity crown fire. The stands were between and 109 years since fire. FUELS WEATHER EXPERIMENTAL FIRES und, surface, ladder, and • The historical weather and Fire tels were sampled in each Weather Index System components stand age/height data was were analysed for the closest Experimental fires in young stands up to 4 years · Experimental fires in microplots also showed since a stand replacing crown fire indicated that a reburn is unlikely in those stands. that the patchy surface vegetation does not burn in these young stands. Only certain materials (i.e., stumps, punky Whenever possible, we performed simultaneous FIRE BEHAVIOR MODELS l, logs) burnt during those experimental despite, sometimes, extreme fire danger ns to observe the effect of different fuels on the fire behavior, while keeping the weather Within the next few months, we will proceed to the integration of the data from: a) the characterization of the fire environment, b) the expert opinion, and c) the experimental fires. That information will be supplemented with fire behavior models such as those presented by Andrews (1986) and Cruz et al. (2002). Our results will be compared with the model presented by Horn Wet Period (1978). Combustion TOPOGRAPHY Thresholds Normal Period his hypothetical The stands selected were located on flat terrain to eliminate the slope effect on fire behavior. Dry Period lel, the attern of fires depends much upon ACKNOWLEDGEMENTS intrinsic shape of the urve of flammability on the occurrence Time Since Last Fire kim, H. S. 1978, Succession, In: R. M. May (ed). Theoretical Ecology: J Analysis and Scientific Publications. Output, p. 107, 201. Horn (1976).

# **C-6 Fuel Type - Conifer Plantation**

(Allowance for variable crown base height)

Experimental Fires in Red Pine Plantation, Petawawa Forest Experiment Station, Ontario

# Limitations of FBP System Fuel Types

- Some allowance for seasonal changes in flammability and stand composition
- Fuel types are static and not "dynamic" in nature (i.e., no variation in fuel complex structure and fire behavior with stand age *per se*)
- Except for C-6, the emphasis todate has been on natural fire-origin forest stands
- There is at present no capacity to alter any crown fuel characteristics, other than crown base height in C-6
- Slash fuel types reflect logging methods and utilization standards of the 1960s

#### **PROMETHEUS – Canadian Wildland Fire Growth Model**

http://www.firegrowthmodel.com/

# **U.S. Fire Behavior Predicition System**

http://www.fire.org

• Based largely on Rothermel's (1972) surface fire rate of spread model involving laboratory test fires and physical theory (some empiricalism)

- Limited validation
- Does not consider duff layer

BehavePlus System now includes Rothermel's (1991) crown fire rate of spread model which is based on an empirically derived multiplier (3.34) between the predicted surface fire rate of spread and a limited number of wildfire observations (8).

Nearly all simulations undertaken in the U.S. regarding the impacts or effectiveness of fuel treatments on fire behavior involve the BehavePlus System (or its derivatives – NEXUS, FARSITE, Fuel Management Analyst), and the Rothermel (1991) model.

# **New Models for Assessing Crown Fire Hazard**

Re-analysis of the experimental data used in the development of the Canadian FBP System undertaken by M.G. Cruz (Univ. MT/ADAI
Portugal), M.E. Alexander & Ron Wakimoto (Univ. MT) in 1999-2005 has lead to the development of more generic-based models for predicting crown fire initiation and spread in conifer forest stands

**Diagram of** information flow for predicting crown fire initiation\* and spread potential based on the models developed by Cruz, Alexander and Wakimoto (2004, 2005).

\*Alternatively, crown fire initiation can be predicting using crown base height, 10-m open wind speed, and FWI System components (Cruz, Alexander and Wakimoto 2003)

# **Model Inputs**

- Estimated Fine Fuel Moisture (determined from air temperature, relative humidity, time of year & day, and degree of shading)
- Surface Fuel Consumption (<1, 1-2 or > 2 kg/m<sup>2</sup>)\*
- Fuel Strata Gap or Canopy Base Height\*
- 10-m Open Wind Speed
- Canopy or Crown Bulk Density\*

\*These three characteristics of a forest stand or fuel complex are subject to manipulation by silvicultural and other vegetation management techniques

# **Canopy or Crown Bulk Density Concept**

Available crown fuel load determined from stand data (i.e., number of stems per hectare by DBH size class) and foliage/twig vs. DBH relationships

Van Wagner's (1977) critical minimum spread rate criterion for active or continuous crowning as related to canopy bulk density (curve) in relation to experimental crown fire data

# **Model Evaluation**

The Cruz, Alexander and Wakimoto (2003, 2004, and 2005) model outputs have been compared to two independent experimental datasets (ICFME & Porter Lake) as well as 57 wildfire observations (43 Canadian & 14 U.S.) obtained from case studies. The results have been quite favourable.

Relative Increases in Fire Intensity and Crowning Potential due to fuel manipulation in a Lodgepole Pine Stand\* near Whitecourt, AB (as described by Dam 2000) based on various fire behavior models

<sup>\*</sup>Dam, J. 2000. Effects of thinning in fire behavior: a case study in lodgepole pine in Canada. M.Sc. Thesis, Wageningen University, Holland. 60 p.

# III. Conclusions & Some Suggestions for the Future

- Fire behavior is a multi-faceted subject area
- While acknowledging that the processes involved are complex with numerous controlling factors, qualitatively we know a great deal about fire behavior
- Fire behavior research and associated model development has matured greatly in recent years
- Rudimentary modelling of fire behavior potential in relation to post-harvest stand development is now possible; such efforts will no doubt identify critical knowledge gaps and research needs

- We know nothing specific about fuel and fire behavior characteristics in young, post-harvest stands in western Canada
- Existing knowledge should be summarized and made available to managers & other researchers in order to continue the process of communication across disciplines
- Consider extension of the Forest Vegetation Simulator to post-harvest stand development as a means of integrating and "housing" our collective knowledge, not just for fire considerations

# Fire behaviour as a factor in forest and rural fire suppression

Martin E. Alexander

Forest Research Bulletin No. 197 Forest and Rural Fire Scientific and Technical Series Report No. 5

... further major advances in combating wildfire are unlikely to be achieved simply by continued application of the traditional methods. What is required is a more fundamental approach which can be applied at the design stage ... Such an approach requires a detailed understanding of fire behaviour ...
